# Lab 07: Wireless and Mobile Networks

**Name:** Dylan Espinoza

**Course:** Networks and Distributed Systems

**Date:** Thursday, November 12, 2026

Through this course, I learned more about how 5G networks are designed to respond to the increasing demand for wireless communication. One of the most interesting aspects was understanding that each generation of mobile networks introduced different improvements, allowing more people and devices to communicate efficiently. I also learned that 5G focuses on reducing communication delays, supporting a higher number of connected devices, and providing more reliable connections for different applications.

Another important topic was the use of radio frequencies and how they influence network performance. I understood that choosing the appropriate spectrum is essential because different frequency bands offer different advantages in terms of coverage and data transmission. The course also helped me recognize the role of international standards, which allow equipment from different manufacturers to operate within the same network. Finally, I realized that implementing 5G requires careful infrastructure planning and technological improvements to meet future communication needs.

## Technical Insights

1. I learned that reducing latency is one of the important goals of 5G, especially for applications that require fast communication and immediate responses.
2. I understood that different frequency bands affect network coverage and capacity, making spectrum selection an important part of wireless network design.
3. I learned that 5G networks must support a large number of connected devices while maintaining stable communication and efficient use of network resources.
